

Real Estate Sales Analysis

Key Findings | Sales Data 2011–2022

This summary distills five key findings from a Tableau-based analysis of residential real estate sales, covering pricing trends, property-type mix, and geographic distribution.

1

Sales activity accelerated sharply after 2011, peaking in 2021

Growth stayed near-zero through the 2000s, then rose steadily, hitting 17.16% year-on-year growth in 2021 before dropping to 9.42% in 2022.

2

Single Family homes dominate the market by value

Single Family homes account for 80.23% of total sale value — nearly six times every other property type combined. Condos are a distant second at 15.03%.

3

No single town or state drives the market

Sales are spread across roughly 50 towns, with the top town holding only about 4% share. Growth is broad-based rather than concentrated in a few dominant locations.

4

Assessed values broadly align with sale prices

Average Sales Ratio sits close to 1.0 across most towns, indicating assessments are generally reliable pricing benchmarks — after excluding a small number of outlier transactions (e.g., \$1 nominal sales linked to non-arm's-length transfers).

5

Data limitations affect confidence in these findings

Early years (1998–2010) show minimal records, and the dataset spans multiple U.S. states with an unusually even sales distribution — atypical for real market data. Findings should be treated as directional until the data source and scope are independently verified.

Applies across all charts

Note on Reliability

This dataset's geographic spread (towns across multiple U.S. states with unusually even sales share) does not match typical real-world real estate market behavior, which is normally more geographically concentrated. Treat these findings as illustrative of the dataset provided, not as a verified market study, until the data source is confirmed.
